

ABSTRACT

Actual caller identification is provided. Biometric information is collected from a calling party. For example, retinal scan or facial recognition information is collected from a calling party. An element of a communications network receives the biometric information and uses the biometric information to determine the identity of the calling party. For instance, the biometric information is used to generate an index or key into an identity database. The index or key is used to retrieve identity information associated with a record including matching biometric information. The identity information is transmitted, for example, to user equipment of a called party.
